

Imagine the yellow dot travelling anticlockwise around the circle.

Now imagine the yellow dot starts at the point $(1,0)$ (where it is shown in the diagram above), turns through 60 degrees anticlockwise and then stops.

I was wondering, if the point hadn't stopped, and instead carried on until it had turned through 30 000 degrees, might it have finished the same distance above the horizontal axis?

I took out my calculator and typed $30\,000 \div 360$.
The answer on the screen was 83.333333.

How can I use this to help me solve my problem?
