

# Perfect Eclipse

Radius of the sun: 695,500km

Radius of the moon: 1,737km

Radius of the earth: 6,371km

Smallest distance between Earth and Sun: 147,098,074km

Largest distance between Earth and Sun: 152,097,701km

Smallest distance between Moon and Earth: 356,375km

Largest distance between Moon and Earth: 406,720km

Here are some issues to consider:

- How much does the apparent size of the moon change, as its distance from the Earth changes?
- How much does the apparent size of the sun change?
- Can there ever be a perfect eclipse?

The Earth revolves round the Sun ovally. Like the picture below, while the Earth is revolving the Sun, the distances between the Sun and Earth, Earth and Moon should be different. It affects how much the Moon's shadow can cover the Sun which means it decides whether it is perfect eclipse or not.

<Method 1>

- Smallest distance

$$\begin{aligned} PA &= (\text{smallest distance between Earth and Moon}) + (\text{Radius of the Moon}) \\ &= 356,375\text{km} + 1,737\text{km} \\ &= 358,112\text{km} \end{aligned}$$

$$\begin{aligned} PB &= (\text{smallest distance between Earth and Sun}) + (\text{Radius of the Sun}) \\ &= 147,098,074\text{km} + 695,500\text{km} \\ &= 147,793,574\text{km} \end{aligned}$$

The radius of Moon's shadow reached Sun

$$PA : PB = 1,737 : x$$

$$358,112 : 147,793,574 = 1,737 : x$$

$$358,112x = 147,793,574 * 1,737$$

$$x = 716,863.5436\dots\text{km}$$

Compare between radius of Sun and radius of Moon's shadow

$$695,500\text{km} < 716,863.5436\dots\text{km}$$

-> the radius of Sun < the radius of Moon's shadow

**The shadow of the Moon**

-> The shadow of the Moon blocks Sun's light perfectly.

- Largest distance

$$\begin{aligned} PA &= (\text{largest distance between Earth and Moon}) + (\text{Radius of the Moon}) \\ &= 406,720\text{km} + 1,737\text{km} \\ &= 408,457\text{km} \end{aligned}$$

$$\begin{aligned} PB &= (\text{largest distance between Earth and Sun}) + (\text{Radius of the Sun}) \\ &= 152,097,701\text{km} + 695,500\text{km} \\ &= 152,793,201\text{km} \end{aligned}$$

The radius of Moon's shadow reached Sun

$$PA : PB = 1,737 : x$$

$$408,457 : 152,793,201 = 1,737 : x$$

$$408,457x = 152,793,201 * 1,737$$

$$x = 649,766.7812... \text{km}$$

Compare between radius of Sun and radius of Moon's shadow

$$695,500\text{km} > 649,766.7812... \text{km}$$

-> the radius of Sun > the radius of Moon's shadow

-> The shadow of the Moon blocks Sun's light partially.

<Method 2>

Formula of calculating angular diameter

$$\delta = 2 \arctan \left( \frac{1}{2} d/D \right)$$

- Smallest distance

$$\begin{aligned} D(\text{Sun}) &= (\text{smallest distance between Earth and Sun}) + (\text{Radius of the Sun}) \\ &= PB + BD \\ &= 147,098,074\text{km} + 695,500\text{km} \\ &= 147,793,574\text{km} \end{aligned}$$

$$\begin{aligned} D(\text{Moon}) &= (\text{smallest distance between Earth and Moon}) + (\text{Radius of the Moon}) \\ &= PA + AC \\ &= 356,375\text{km} + 1,737\text{km} \\ &= 358,112\text{km} \end{aligned}$$

$$\begin{aligned} d(\text{Sun}) &= (\text{diameter of Sun}) \\ &= (\text{radius of Sun}) \times 2 \\ &= BD \times 2 \\ &= 695,500 \times 2 \\ &= 1,391,000\text{km} \end{aligned}$$

$$\begin{aligned} d(\text{Moon}) &= (\text{diameter of Moon}) \\ &= (\text{radius of Moon}) \times 2 \\ &= AC \times 2 \\ &= 1,737 \times 2 \\ &= 3,474\text{km} \end{aligned}$$

Find an angular diameter:

Sun

$$\begin{aligned} \theta &= 2\arctan(1/2 \times 1,391,000 / 147,793,574) \\ &= 0.539251057\dots \\ &= 32'35.50'' \end{aligned}$$

Moon

$$\begin{aligned} \theta &= 2\arctan(1/2 \times 3,474 / 358,112) \\ &= 0.5558148766\dots \\ &= 33'34.88'' \end{aligned}$$

-> The shadow of the Moon blocks Sun's light perfectly.

- Largest distance

$$\begin{aligned}D(\text{Sun}) &= (\text{largest distance between Earth and Sun}) + (\text{Radius of the Sun}) \\ &= PB + BD \\ &= 152,097,701\text{km} + 695,500\text{km} \\ &= 152,793,201\text{km}\end{aligned}$$

$$\begin{aligned}D(\text{Moon}) &= (\text{largest distance between Earth and Moon}) + (\text{Radius of the Moon}) \\ &= PA + AC \\ &= 406,720\text{km} + 1,737\text{km} \\ &= 408,457\text{km}\end{aligned}$$

$$\begin{aligned}d(\text{Sun}) &= (\text{diameter of Sun}) \\ &= (\text{radius of Sun}) \times 2 \\ &= BD \times 2 \\ &= 695,500 \times 2 \\ &= 1,391,000\text{km}\end{aligned}$$

$$\begin{aligned}d(\text{Moon}) &= (\text{diameter of Moon}) \\ &= (\text{radius of Moon}) \times 2 \\ &= AC \times 2 \\ &= 1,737 \times 2 \\ &= 3,474\text{km}\end{aligned}$$

Find an angular diameter:

Sun

$$\begin{aligned}\theta &= 2\arctan(1/2 \times 1,391,000 / 152,793,201) \\ &= 0.5216061863\dots \\ &= 31^\circ 29.63''\end{aligned}$$

Moon

$$\begin{aligned}\theta &= 2\arctan(1/2 \times 3,474 / 408,457) \\ &= 0.4873079373\dots \\ &= 29^\circ 23.84''\end{aligned}$$

-> The shadow of the Moon blocks Sun's light partially.

The shadow of the Moon covers the Sun if those planets' positions are at the smallest distance. In other words, the perfect eclipse occurs when the moon is between the sun and the earth at the smallest distance. In contrast, if the Moon is the farthest to the Sun, the Moon's shadow cannot cover all part of the Sun which is the partial eclipse.
